This invention proposes a feature based data structure for computer manikin that is constructed from scanned data of common 3D body scanners. The scanned data is first segmented into six parts and then encoded into range images. Feature recognition algorithms are developed and coded into computer algorithms. The can automatically recognize t h e software system important human feature points and feature curves. The i s computer manikin constructed based interpolation between the feature curves. The manikin has geodetic latitudinal and longitudinal curves that pass through the geometric feature points of human body. The geodetic coordination contains all the important features that can be extracted as needed for apparel or design, medical researches, a n d ergonomic movie amusement industry.
